# A Review of Organosilanes in Organic Chemistry

- Silyl Protecting and Derivatisation Reagents
- Organosilanes as Reducing Agents
- Silanes in Cross-coupling Chemistry
- Allylsilanes Used to Stabilize  $\alpha$ -Carbanions and  $\beta$ -Carbocations

# INTRODUCTION

Organosilanes have varied uses in organic chemistry from the most frequently employed protecting groups to intermediates in organic synthesis. The Acros Organics portfolio of organosilanes is continuously expanding to meet your chemistry needs. In this brochure you will find an overview of four of the most important applications of organosilanes:

- Silyl Protecting and Derivatisation Reagents<sup>1,2</sup>
- Organosilanes as Reducing Agents<sup>3</sup>
- Silanes in Cross-coupling Chemistry<sup>4</sup>
- Allylsilanes Used to Stabilize  $\alpha$ -Carbanions and  $\beta$ -Carbocations<sup>4</sup>

## Silyl Protecting and Derivatisation Reagents

Silicon protecting groups are probably the most frequently employed of all protecting groups, and modern natural product synthesis is inconceivable without them.<sup>5</sup> Silylating agents are mostly used to protect alcohols and phenols, but have also found application in the protection of amines, carboxylic acids, amides, thiols and alkynes.

By varying the substituents attached to silicon, the steric and electronic characteristics of the protecting group can be finely tuned, allowing a wide variety of both reaction and deprotection conditions. The leaving group also plays an important role in the reactivity and use of silylating reagents. Whilst chlorotrimethylsilane [product code: 42643] liberates hydrogen chloride on reaction, other TMS protection reagents liberate neutral or basic by-products. For example, *N,N*-Diethyl-1,1,1-trimethylsilylamine [15569] is a moderately strong silylating reagent liberating volatile diethylamine, while allyltrimethylsilane [19699], used to protect acids and thiols, generates gaseous propene as a by-product.<sup>6</sup>

The high affinity of silicon for fluorine is particularly advantageous, permitting deprotection of the silyl group with tetrabutylammonium fluoride [20195], a reagent that is compatible with a wide range of orthogonal protecting groups and other functional groups. The actual stability of a silyl protecting group depends on the pH of the medium, the exact reaction conditions, steric and electronic effects but, in general terms, the stability to hydrolysis increases:<sup>7</sup>

### Acidic hydrolysis:

### Basic hydrolysis:

Acros Organics have recently introduced a range of commonly used silyl chlorides (shown in the table on page 3) in AcroSeal<sup>®</sup> packaging, allowing easy handling and excellent stability of these moisture-sensitive protecting reagents.

The Acros Organics range includes many synthetic intermediates with silyl protection already in place. A selection of typical products is illustrated here. For more examples, see the product list at the end of this brochure or visit [www.acros.com](http://www.acros.com).

## A selection of Organochlorosilane Protecting Group Reagents available from the AcroSeal® range:

Group	Reagent	Code	Notes
Me <sub>3</sub> Si (TMS)	Chlorotrimethylsilane	42643	Used for the protection of alcohols, alkynes, amines and amino acids, carboxylic acids, phenols, ketones. Most easily cleaved of all silyl protecting groups in acid and base.
	Chlorotrimethylsilane, 1M solution in THF	38161	
	Chlorotrimethylsilane, 1M solution in DCM	38160	
Et <sub>3</sub> Si (TES)	Chlorotriethylsilane, 1M solution in THF	43325	Used for the protection of alcohols. TES ethers can be selectively deprotected in the presence of TBDMS ethers <sup>8</sup> .
<sup>t</sup> BuMe <sub>2</sub> Si (TBDMS)	<i>tert</i> -Butyldimethylsilyl chloride, 1.0M in DCM	36910	Used for the protection of alcohols, amines, thiols, lactams and carboxylic acids. Reaction with an alcohol requires a catalyst such as imidazole. [20094] is a convenient, ready-to-use DMF solution of TBDMSCl (0.5M) and imidazole (1.0M).
	<i>tert</i> -Butyldimethylsilyl chloride, 50 wt.% in PhMe	43311	
	BDCS, silylation reagent	20094	
<sup>t</sup> BuPh <sub>2</sub> Si (TBDPS)	<i>tert</i> -Butylchlorodiphenylsilane	43092	Greater steric demand. Therefore, more stable than TBDMS to acid hydrolysis (>100x). Primary alcohols are protected in the presence of secondary alcohols.
Ph <sub>2</sub> Si	Dichlorophenylsilane	43089	Used for the protection of diols, diamines and hydroxyacids. <sup>9</sup>

Derivatisation of a compound by reaction with a silylating agent is of particular utility in gas chromatography (GC) analysis. Molecules containing functional groups such as carboxylic acid, hydroxyl, amine, thiol and phosphate, which may be difficult to analyse by GC, can be readily converted into silylated derivatives that are generally less polar, more volatile and have greater thermal stability and are, therefore, more suitable for GC analysis.

### Typical Derivatisation Reagents from Acros Organics

Derivatisation Reagent	Code	Structure	Notes
N,O-Bis(trimethylsilyl)acetamide	15646		Commonly used derivatisation agents for acidic functional groups; i.e., alcohols, enols, amines, amides, carboxylic acids, amino acids, phenols, steroids, biogenic amines, alkaloids, phosphites and thiols. <sup>2, 10</sup>
N,O-Bis(trimethylsilyl)trifluoroacetamide	16800		One of the most potent silylation reagents used today. It has two advantages over BSA in GC analysis: i) The by-products and the reagent itself are highly volatile so they cause minimal interference with the GC analysis. ii) The presence of fluorine atoms results in less fouling of flame-ionisation detectors. [38932] contains 1% TMSCl, which increases the silylating power of the mixture for analytical derivatisations.
N,O-Bis(trimethylsilyl)trifluoroacetamide, with 1% TMSCl	38932		
N,O-Bis(trimethylsilyl)trifluoroacetamide, packaged in 1 ml ampoules	32120		
N-Methyl-N-(trimethylsilyl)trifluoroacetamide (MSTFA)	22158		MSTFA and its by-product are even more volatile than BSTFA and its by-product. Used in the analysis of steroids <sup>11</sup> , fatty acids <sup>12</sup> and nucleic acids by GC/MS.
Dichloromethylsilane AcroSeal®	43088		Used for derivatisation of diols, diamines and hydroxyacids.

# Organosilanes as Reducing Agents

Organosilanes with one or more hydrogen atoms attached to silicon have the ability to behave as either ionic or free-radical reducing agents. Changing the groups attached to silicon modifies the character of the Si-H bond and allows the organosilane reagent to be tailored to give a particular type of reduction. Substrates that can form a stable carbenium ion intermediate such as alcohols, olefins, esters, lactones, aldehydes, ketones, acetals, ketals and imines are reduced with reagents like triethylsilane [21292], which is used in combination with an acid. Triphenylsilane [16482] and tris(trimethylsilyl)silane [29106] are used for free radical reductions, in place of tri-*n*-butyltin hydride.<sup>13</sup> The breadth of reductions possible with organosilanes is illustrated below. These organosilanes and the reduction by-products are generally safer and more easily handled and disposed of than traditional reducing agents such as lithium aluminium hydride and tributyltin hydride.

The ease of reduction of various functional groups with silyl hydrides, available from Acros Organics

## Hydrosilylation

Alkynes, alkenes and ketones undergo free radical hydrosilylation with silyl hydrides. The regio- and stereocontrol is dependant upon the substrate substituents, the organosilane and the particular catalyst used. For example,  $\alpha$ -vinylsilanes have been prepared in high yield by reaction of triethoxysilane [16481] with a range of terminal alkynes in the presence of [CpRu(MeCN)<sub>3</sub>]PF<sub>6</sub> [37789].<sup>14</sup>

# Silanes in Cross-coupling Chemistry

Many metal-catalysed coupling methods have been developed for the formation of carbon-carbon bonds, utilising a range of organometallic species. Examples include Stille (Sn), Kumada (Mg), Suzuki (B) and Negishi (Zn) coupling. For an overview of these methodologies, the Acros Organics “Palladium Catalysed Coupling Chemistry” brochure is available at [www.acros.com](http://www.acros.com).

The Hiyama coupling is typically a palladium- or nickel-catalysed coupling of organohalides or triflates with organosilanes.<sup>15</sup> The use of organosilanes in place of organometallic reagents (Mg, Zn and Sn) is often advantageous due to their low toxicity, chemical stability and ease of handling.

The coupling reaction is promoted by activation of the organosilane with a fluoride source, converting the silicon compound  $\text{RSiR}'_3$  to a  $\text{RSi-R}'_3\text{F}$  intermediate that is more amenable to transmetalation. Alternatively, a strong base can be used. Many organosilicon compounds can undergo coupling reactions, including dialkylsilanols<sup>16</sup> and trialkoxysilanes.

## Trialkoxysilanes

Trimethoxy and triethoxysilanes are readily prepared from an organometallic species<sup>17, 18</sup> by reaction with tetramethyl orthosilicate [20382] and tetraethyl orthosilicate [42036] or by transition metal-catalysed silylation<sup>19</sup> with triethoxysilane [16481]. Organotrimethoxysilanes have been successfully applied as coupling reagents in the Hiyama coupling reaction with aryl chlorides and bromides, vinyl halides, aryl triflates, and allylic benzoates.<sup>20, 21, 22</sup>

Recently, an efficient Hiyama coupling reaction between benzylic halides and aryltrialkoxysilanes using Pd nanoparticles has been developed, accommodating many functional groups and leading to the synthesis of a diverse range of diarylmethanes in high yield.<sup>23</sup> No expensive ligands are required to generate the catalyst, which is prepared by stirring  $K_2PdCl_4$  [19512] with PEG-600 [19224] for 15 minutes at 70°C. PEG acts as both a stabilizing and reducing agent.

Styrenes have been prepared in high yield by reaction of vinyltrimethoxysilane [43306], triethoxyvinylsilane [17461] and vinyl tris(2-methoxyethoxy)silane [25051] with aryl halides in aqueous sodium hydroxide, under conventional or microwave heating. Ligandless  $Pd(OAc)_2$  [19518] acts as an efficient source of Pd nanoparticles at low loading (0.1 mol % Pd).<sup>24</sup>

## Dimethylsilanols

Aryl and alkenyl dimethylsilanols can be easily synthesised by direct metallation of heterocycles or by metal-halogen exchange of aryl or alkenyl halides, followed by quenching with hexamethylcyclotrisiloxane [21646] or dichlorodimethylsilane [11331]. Denmark *et al.*<sup>25</sup> have developed methodology to allow the efficient cross coupling of heteroaryldimethylsilanols with aryl iodides in the presence of  $Pd_2(dba)_3 \cdot CHCl_3$  [36934]. Cross coupling of Boc-protected dimethyl(2-indolyl)silanol is particularly difficult due to decreased nucleophilicity at C-2. They found that silanolates generated *in-situ* from NaO<sup>t</sup>Bu undergo Pd-catalysed cross coupling with aryl iodides in the presence of CuI, while silanolates generated with NaH couple without an additive. The methodology was extended to thiophene, furan and pyrrole nucleophiles with both electron-deficient and electron-rich aryl iodides.

# Allylsilanes Used to Stabilize $\alpha$ -Carbanions and $\beta$ -Carbocations

Silicon, being more electropositive than carbon, exerts a considerable electronic effect on carbons  $\alpha$  and  $\beta$  to it in an organic molecule. Silanes that are activated in the  $\alpha$  position can form stabilised carbanions, enhancing their reactivity to metallation, and subsequent reaction with an electrophile. Stabilisation of a carbocation on the  $\beta$  carbon allows electrophilic substitution in vinyl, aryl, allyl or alkynyl silanes, with the silyl group acting as a leaving group.

Allylsilanes are useful intermediates in organic synthesis as the silicon is capable of stabilising both  $\alpha$ -anionic charges and  $\beta$ -cationic charges.<sup>26</sup>

Simple allylsilanes are made directly by silylation of a metal allyl species, but other approaches are used to construct more complex systems.

In the synthesis of the tricyclic core of neoliacinic acid,<sup>27</sup> the allylsilane (A) was required for the introduction of the side chain. Treatment of the ester [43618] with an organocerium reagent, generated by reaction of trimethylsilylmethylmagnesium chloride [37746] with anhydrous cerium (III) chloride, resulted in a double Grignard addition of  $TMSCH_2^-$ . After workup, exposure of the tertiary alcohol to silica gel facilitated the Peterson elimination, providing the required allylsilane with predictable regiochemistry.

Allylsilanes react regioselectively with a variety of electrophiles in the presence of a suitable Lewis acid to give allylic products. The TMSOTf [20944]-catalysed reaction of (3-methylcyclohex-1-enylmethyl)trimethylsilane [33904] with 1,1-diethoxyethane [10222] gives racemic allylic product in 79% yield.<sup>28</sup>
